Zerone tutorial

Pol Cuscó and Guillaume Filion October 20, 2015

1 Building instructions

Zerone is available as a Linux command line application and as an R package.

1.1 Downloading

We recommend that you use git to keep Zerone updated. You can clone the repository from Github with the following command on a standard terminal.

```
git clone git@github.com:gui11aume/zerone
```

Note that this requires that you already have a Github account and that the computer you are working on has an SSH key registered on GitHub. If this is not the case, follow the instructions from https://help.github.com/articles/generating-ssh-keys/.

Alternatively, if you prefer not to use git, you can download the source code from https://github.com/guillaume/zerone/archive/master.zip with the following commands.

```
wget https://github.com/guillaume/zerone/archive/master.zip
unzip zerone-master.zip
mv zerone-master zerone
```

This should create a directory named zerone.

1.2 Compiling

To build Zerone, execute the following from the zerone directory.

```
cd zerone
```

This should succeed on most Linux systems because make is available by default. If this is not the case, you can obtain it by typing sudo apt-get install make on the Ubuntu terminal.

Calling make should create an executable called zerone.

1.3 Testing

To check that the building was successful, test Zerone with the following commands.

```
cd src/test
make test
cd ../..
```

If it passes the tests without any error message, then everything went fine and you are done with the build. If not, something went wrong. In this case, you can explain how to reproduce the problem on https://github.com/guillaume/zerone/issues.

Installing Rzerone

To install the Rzerone R package, simply run this command from the zerone directory.

R CMD INSTALL Rzerone

Note that you need to have R installed on your computer. If this is not the case, run the command sudo apt-get install r-base on Ubuntu.

2 Zerone basics

To run Zerone, you have to specify the files that contain the mapped reads of the ChIP-seq experiment you want to discretize. These can be in BED, SAM/BAM and GEM (.map) formats. You can include as many negative control files and as many experimental replicates as you need. Just enter controls after the -0 or --mock option, and targets after the -1 or --chip option.

For example, you can type in the following commands from the zerone directory.

```
./zerone --mock file1.bam,file2.bam --chip file3.bam,file4.bam
```

Where file1.bam and file2.bam are negative controls done without antibody, and file2.bam and file3.bam are two experimental replicates.

This should produce an output like the following.

chrX	1	300	0	0	0	0
\mathtt{chrX}	301	600	0	0	0	0
\mathtt{chrX}	601	900	0	0	0	0
chrX	901	1200	0	0	0	0
\mathtt{chrX}	1201	1500	0	0	0	0
chrX	1501	1800	0	0	0	0
\mathtt{chrX}	1801	2100	0	0	0	0
\mathtt{chrX}	2101	2400	0	0	0	0

Note that path expansion will not work when using comma separated file names, so if ou want to use path names starting with \sim , you can simply specify the mock and chip options as many times as needed, as shown below.

```
./zerone -1 -0 file1.map -1 file2.map -1 file3.map
```

With the $\neg 1$ or $\neg \neg 1$ ist $\neg o$ utput option, Zerone produces an alternative, BED-like output.

1	600
601	1200
1201	1800
1801	2400
2401	3000
3001	3600
3601	4200
4201	4800
	601 1201 1801 2401 3001 3601

Enter the option -h or --help for usage instructions and --version to print the version number.

3 Troubleshooting

In case Zerone crashes, start by recompiling it in debug mode. To do so, run the following commands from the zerone directory.

```
make clean
make debug
```

Then repeat the actions that triggered the crash and contact guillaume.filion@gmail.com attaching the debug information.
